DEDICATION

I dedicate this work to Almighty Allah for His guidance, blessing and protection throughout this research work and also to my family members for their support and understanding.

ACKNOWLEDGEMENTS

I am grateful to Almighty Allah for giving me the patience to complete this work. I would like to express my deepest and sincere thanks and gratitude to my supervisor Prof. K. J. Osinubi for his unconditional motivation, contributions and advice towards the attainment of this research work. I am also grateful to Dr T. S. Ijimdiya for contributions and guidance in making this research successful. I will like to recognize and acknowledge the guidance and useful contribution of Dr. A. O. Eberemu and Engr. J. Ochebo throughout this research work.

I am also indebted to the Head of Department, Dr. Y. D. Amartey, Postgraduate Coordinator, Dr. J. Sadeeq, Prof. S. P. Ejeh, Dr. O. S. Abejide, Dr. A.T. Olowosulu, Dr. A. Ocholi and Dr. I. Abubakar for their contributions to my success. Furthermore, I will not fail to appreciate the following persons whose contributions assisted in making this project a success, Engr H.S. Samaila, John Sani, Frederick Kigha, Godwin Lazhi, Ishola Kazeem and to the entire staff of soil research laboratory of Civil Engineering, Ahmadu Bello University, Zaria.

ABSTRACT

Results of preliminary investigation of the natural black cotton soil used in the study shows that it belongs to A – 7 – 6 (13) or CH in the AASHTO and Unified Soil Classification System (USCS), respectively. Soils under these groups are highly plastic and of poor engineering benefit. The soil was treated with up to 16% iron ore tailing, IOT (a mining waste) by dry weight of soil and compacted using three energy levels (British Standard light, BSL, West African Standard, WAS and British Standard heavy, BSH). Tests were carried out to determine index properties, compaction characteristics, strength characteristics, durability and microanalysis of specimens. Test results showed an increase in the particle sizes with higher IOT content as particle size distribution curves shifted from the region of fine-grained soils to coarse-grained soil. The liquid limit and plastic limit initially increased from 64.5 and 25.0% for the natural soil to peak values of 71.0 and 34.9 % for 2 and 8% IOT treatments, respectively, and thereafter decreased with higher IOT treatments to 59.9 and 27.5% at 16% IOT content. The linear shrinkage generally reduced with higher IOT treatment from 27.14% for the natural soil to 18.0% at 16% IOT content. Generally, the maximum dry density (MDD) increased while optimum moisture content (OMC) decreased with higher IOT treatment. The 7day unconfined compressive strength (UCS) values for the natural soil are 172.59, 328.38 and 448.83 kN/m² when compacted with BSL, WAS and BSH energies, respectively, increased to peak values of 337.77, 487.57 and 821.57 kN/m² at 16, 10 and 12% IOT contents, respectively. However, the recorded values did not meet the 1034.25 or 1710 kN/m² requirement for adequate lime or cement stabilization, respectively. Similarly, the California bearing ratio (CBR) values (unsoaked) of the compacted natural soil increased from 7.89, 9.82 and 15.03 % to peak values of 16.62, 19.64, and 29.06% at 12, 14 and 12% IOT using BSL, WAS and BSH energies, respectively. For the 24 hour soaked condition the CBR values of 3, 4 and 5 % for the natural

soil increased to 5.66, 8.69 and 11.33% for BSL, WAS and BSH compactive energies at 12% IOT treatments. The resistance to loss in strength increased from 10.81, 11.84 and 13.09 % for the natural soil to peak values of 24.71, 24.73 and 17.18% at 8, 12 and 10 % IOT treatments for BSL, WAS and BSH compactions, respectively. Microanalysis of specimens treated with an optimal 10% IOT and statistical analysis of the results using the analysis of variance (ANOVA) showed that the soil characteristics improved. The results recorded show that although iron ore tailing (IOT) improved the properties of black cotton soil (as demonstrated by its statistically significant effect on soil properties), however, it cannot be used as a stand-alone stabilizer but in admixture stabilization of the soil.

CHAPTER ONE
INTRODUCTION

Formatted

1.1 Preamble

The stability of structures founded on soil depends to a large extent on the interaction of the said soil with water. Some soils of the tropics (e.g., black cotton soil), absorb large amount of water during the rainy seasons and do not allow easy passage of such water. This consequently results in a large volume increase which drastically reduces during the dry season. This phenomenon has substantial effect on structures founded on such soils. Also, road bases built with soils that are not easily drained are affected by the development of pore water pressures which causes the formation of potholes and, eventually, the total failure of such roads. In an attempt to minimize these effects, such soils are subjected to treatments aimed at either disallowing water into them or allowing easy passage (drainage) of water to prevent pore water build up (Alhassan, 2008).

Problematic soils such as expansive soils are normally encountered in foundation engineering designs for highways, embankments, retaining walls, backfills, etc. Expansive soils are normally found in semi – arid regions of tropical and temperate climate zones and are abundant where the annual evaporation exceeds the precipitation (Chen, 1988; Warren and Kirby; 2004).

Black cotton soil is an expansive soil (Tomlinson, 1999; Osinubi et al., 2010). It is found in the north eastern part of Nigeria, Cameroon, Lake Chad Basin, Sudan, Ethiopia, Kenya and South Zimbabwe. The soil is also found in India, Australia, south west of United States of America (Ola, 1978), South Africa and Israel (Plait, 1953).

Two groups of parent rock materials have been associated with the formation of expansive soils. The first group comprises sedimentary rock of volcanic origin, which can be found in North America, South Africa and Israel (Plait, 1953), while the second group of parent materials are basic igneous rocks found in India, Nigeria and South Western U.S.A. (Medjo and Riskowiski, 2004). Morin, (1971) gives the engineering definition for black cotton soil as dark grey to black soil with a high content of clay, usually over 50 % in which montmorillonite is the principal clay mineral and which is commonly expansive. They have the tendency to expand and shrink with changes in moisture and appreciable plasticity due to the clay fraction.

Black cotton soils are expansive soils also referred to as tropical black clay. They are so named because of their suitability for growing cotton. Black cotton soils have varying colours' ranging from light grey to dark grey and black. The mineralogy of this soil is dominated by the presence of montmorillonite which is characterized by large volume change from wet to dry seasons and vice versa. Deposits of black cotton soil in the field show a general pattern of cracks during the dry season of the year. Cracks measuring 70 mm wide and over 1 m deep have been observed and may extend up to 3m or more in case of deep deposits (Adeniji, 1991). These soils are poor materials to employ for highway or airfield construction because they contain high percentages of plastic clay. In areas where they occur, usually there are no suitable natural gravels or aggregates and most deposits cover significantly large areas that avoiding them is not possible.

Although poor and undesirable for engineering purposes, its properties could be improved to meet standard specification by stabilization processes. Stabilization of the soil with chemical admixtures is a common method of reducing the swell – shrink tendencies of the soil and also makes the soil less plastic (Ola, 1983; Balogun, 1991; Osinubi, 1995; 1999). In traditional practices, stabilizers such as cement, lime, and bitumen, alone or in combination, are used as additives to stabilize soils. However, there is a variety of non-traditional soil stabilization/modification additives available from the commercial sector such as polymer emulsions, acids, lignin derivatives, enzymes, tree resin emulsions, and silicates. To achieve stability, the additive must be incorporated with the soil (Newman and Tingle, 2004).

Researchers (Ola, 1983, Balogun, 1990, Osinubi, 1995, 1999, Osinubi and Medubi, 1998) reported that appreciable improvements in the geotechnical properties of black cotton soils were observed when treated with lime, as well as lime admixed with cement. The need to reduce the rising cost of soil stabilizers and overdependence on industrially manufactured soil improving additives (cement, lime, etc.), has led to intense global research towards economic utilization of wastes for engineering purposes (Oriola and Moses, 2010).

Research works (Mohammedbhai and Baguant, 1990; Osinubi, 1997; Osinubi and Stephen, 2005; Osinubi et al., 2009) in the field of geotechnical engineering focus on the search for cheaper and locally available materials for use in stabilization. A large percentage of such materials are agricultural wastes that produce cementitious compounds on addition of moisture. These studies tried to match the need for safe and

environmental disposal of waste, for the society, and the engineer's need for better and cost effective construction materials (Collins and Ciesielski, 1993).

Itakpe iron ore deposit, with an estimated reserve of about 200 million tons, was found in 1977 (Ola et al., 2009). The deposit is embedded in the Itakpe Hill near Okene in the north-central Kogi State of Nigeria.

Itakpe iron ore processing plant produces a waste material of about 64 % of its capacity. At a production rate of 4,737 tonnes/day, large quantities of tailings are obtained as waste product of the beneficiated iron ore (Adepoju and Olaleye, 2001). The management of tailings from iron ore mines is an important issue, from the point of view not only of pollution control but also of the conservation of resources (Ghose, 1997).

1.2 Statement of the Problem

Black cotton soils belong to the smectite group, which includes montmorillonite that are highly expansive and are the most troublesome clay minerals when encountered in construction. Primarily, the problem that arises with regard to expansive soils is that their deformations are significantly greater than the elastic deformations and therefore cannot be predicted by classical, elastic or plastic theory. Movement is usually in an uneven pattern and of such a magnitude as to cause extensive damage to the structures and pavements resting on them (Nelson and Miller, 1992).

Black cotton soils pose great threat and dangers to engineering structures because of their expansive characteristics. Expansive soils cause more damage to structures, particularly light buildings and pavements, than any other natural hazards, including earthquakes and floods (Jones and Holtz, 1993).

Though such damages are yet to be quantified in Nigeria, evidence of colossal damages on buildings and road pavements are very obvious in regions of the country especially in the North – eastern part of the country where black cotton soil exists extensively (Osinubi, 1995). Because of the above mentioned problems and because the black cotton soils occupy an estimated area of 104,000 km² in the north- eastern part of Nigeria, there is need to further investigate cost-effective ways of stabilizing them.

1.3 Justification for the Study

The rising cost of traditional additives such as cement and lime has motivated the search for cheaper and locally available materials for improving problematic or deficient soils to meet geotechnical engineering requirements in the construction industry. The safe disposal of industrial and agricultural waste products demands urgent and cost effective solutions because of the debilitating effect of these materials on the environment and to the health hazards that these wastes constitute (Oriola and Moses, 2010).

Recent trend in research works in the field of geotechnical engineering and construction materials (Osinubi, 1997; Osinubi, 2000a,b; Cokca, 2001; Medjo and Riskowski, 2004; Moses, 2008; Osinubi and Medubi, 1997 a,b; Osinubi and Eberemu, 2005; Osinubi and Stephen, 2005, 2006a,b; Osinubi et al., 2007a,b; 2008a; Osinubi and Eberemu, 2009) focused more on the search for cheap and locally available materials such as bagasse ash, fly ash, blast furnace slag etc. as stabilizing agents for the purpose of full or partial replacement of traditional stabilizers.

Therefore, the possible use of other locally available industrial and agricultural wastes (such as iron ore tailings) with pozzolanic properties as possible substitutes or as admixtures to main stabilizers to modify/stabilize black cotton soils, will considerably reduce the cost of construction and as well as reduce or eliminate the environmental hazards caused by such wastes.

1.4 Aim and Objectives of the Study

The aim of this research was to evaluate the effect of iron ore tailing (a by-product of mining process) when used to stabilize black cotton soil.

The following specific objectives were designed to be achieved:

1. Determination of the oxide compositions of iron ore tailing and black cotton soil.
2. Determination of the moisture – density relationships of the natural and treated soil using various compactive efforts (i.e., British Standard light, West African Standard and British Standard heavy.)
3. Evaluation of cation exchange capacity (CEC)
4. Determination of the strength and durability properties of the treated soil.
5. Determination of the optimal quantity of iron ore tailing needed to stabilize black cotton soil
6. Microanalysis of optimally treated black cotton soil
7. Statistical analysis of the results using analysis of variance (ANOVA) method

The parameters that were investigated include:

Atterberg limits, compaction characteristics (i.e., dry density and moisture content), unconfined compressive strength (UCS), California bearing ratio (CBR) and durability.

1.5 Scope of the Study

This research was carried out to determine the suitability of iron ore tailing (IOT) as additive for black cotton soil stabilization. Tests were carried out to determine the effect of IOT at various compactive efforts (British Standard light (BSL), West African Standard (WAS) and British Standard heavy (BSH)) on the properties of black cotton soil. All tests were carried out in accordance with procedures outlined in BS 1377 (1990) and BS 1924 (1990).

1.6 Research Methodology

All tests on the natural and stabilized soil were carried out in accordance with BS 1377 (1990) and BS 1924 (1990), respectively. Black cotton soil was treated with IOT in stepped concentrations of 0, 2, 4, 6, 8, 10, 12, 14 and 16 % by dry weight of the soil.

The following tests were carried out:

1. Sieve analysis
2. Atterberg limits
3. Compaction
4. Unconfined compression
5. California bearing ratio
6. Cation exchange capacity
7. Microanalysis of specimens
8. Durability

CHAPTER TWO

LITERATURE REVIEW

2.1 Expansive soils

Expansive soil is a type of clayey soil which expands when it comes in contact with water and shrinks when the water evaporates. This soil is generally found in arid and semi-arid regions of the world. A lot of damages occur on structures founded on this type of soil. The damages normally appear as cracks on buildings, canal beds and linings, pavements, lifting of water supply pipeline and sewerage lines, etc. (Sabat, 2012).

Expansive soils owe their expansive character mainly to the constituent clay mineral. The most important clay mineral, which is the cause for expansive nature is montmorillonite. It has an octahedral sheet sandwiched between two silica sheets. When this mineral is exposed to moisture, water is absorbed between interlayering lattice structures and exert an upward pressure. This upward pressure, known as swelling pressure, causes most of the damages associated with expansive soils. Most of the structural damage by expansive soils results from the differential rather than the total movement of the foundation soil as a result of swelling (Holtz and Hart, 1978).

An example of expansive soils is the black cotton soil which is dark–grey to black in colour. The name originated from India where locations of these soils are favourable for growing cotton. It is also the Nigerian type of expansive soils (Osinubi, 1999).

2.1.1 Origin of black cotton soil

Tropical black clay otherwise known as Canada’s swelling clays, India’s black cotton soil and Kenya black cotton soils can be found all over the world (Chen, 1988).

Black cotton soils are black clays that are produced from the breakdown of basic igneous rocks, where seasonal variation of weather is extreme. Nigerian black cotton soils (BCS) are formed from the weathering of shaly and clayey sediments and basaltic rocks. The Nigerian BCS contains more of the montmorillonite mineral with subsequent manifestation of swell properties and expansive tendencies (Ola, 1983). Black cotton soils are confined to the semi-arid regions of tropical and temperate climatic zones and are abundant where the annual evaporation exceeds the precipitation (Chen, 1988; Warren and Kirby; 2004).

Balogun (1991) reported that black cotton soils occur in continuous stretches as superficial deposits and are typical of flat terrains with poor drainage. The absence of quartz in the clay mineralogy enhances the formation of fine-grained soil material, which is impermeable and waterlogged. Other conditions favouring the formation of black cotton soils are evaporation exceeding precipitation, poor leaching, alkaline conditions and retention of magnesium and calcium in the soil (Ola, 1983).

2.1.2 Mineralogical and chemical composition of black cotton soil

Ola (1983) showed that the Nigerian black cotton soils contains about 70 % montmorillonite and 30 % kaolinite and the predominance of this montmorillonite is due to the weathering of the basic constituents. The swell and shrink characteristics of the soil are largely due to montmorillonite mineral while kaolinite is likely responsible for high strength value because of its inability to swell with absorbed water.

The montmorillonite clay structure consists of layer sheet formed and stacked one above the other and the bonding between successive layers is by van der Waals forces

and by cation that may be present to balance charge deficiencies in the structure. These bonds are however, weak and easily separated by cleavage or adsorption of water and other liquids. There is an extensive isomorphous substitution for aluminium and silicon with its lattice which gives the clay a net negative charge resulting in the water absorbing tendencies and an attraction for hydroxyl ions and water molecules to the clay surface (Nelson and Miller, 1992). On the other hand, kaolinite is a relatively inactive clay mineral. Its structure is made of repeating layers of elemental silica-gibbsite sheets in 1:1 lattice (Das, 1998).

2.2 Iron Ore Tailing

Tailings are the discarded material resulting from the concentration of ore during beneficiation operations. Tailings are characterized by fine particle size and varying mineralogical and chemical composition (Aleshin, 1978).

The iron ore extracted from the mines are beneficiated to separate out the valuable mineral content. The prime function of beneficiation of iron ore is to improve the iron (Fe) content and to decrease the Alumina / Silica ratio for smooth blast furnace operations. The left over residue of the iron ore after the beneficiation which usually constitutes of fine particles mixed in a slurry form, known as tailings are needed to be disposed of in the tailings pond for containment. Tailings contain all other constituents of the ore but the extracted metal, among them heavy metals and other toxic substances that are either added to the tailings in the milling process or available with the ore before that (ICOLD, 2003). Therefore, tailings are the waste silica and quartz particles, as well as

fine-grained ore that are unable to be recovered within the existing concentration processes.

The Itakpe iron ore deposit in Nigeria which has a total estimated reserve of about 182.5 million metric tonnes consists mainly of quartzite with magnetite and haematite and the Itakpe project was designed to treat a minimum of 24,000 tons of ore per day and operate 300 days per year (Ajaka, 2009). The deposit contains a mixture of magnetite and hematite with ratio varying throughout the deposit. The ore consists of coarse, medium and fine grained particles. The fine ores are located mainly in the eastern part of the deposit and in thin layers, while the coarse and medium ores are relatively mixed. However, the coarse ore predominates in the north and west of the central layers while the medium one does in the centre of the central layers. The average iron content of the ore deposit was determined to be approximately 35% (Ola et al., 2009).

The disposal of tailings is a major environmental problem, which is becoming more serious with increasing extraction of lower grade deposits. The tailings are usually transported and deposited as slurry of high water content into a massive pond for containment, which are generally called as tailing ponds / tailing dams (CPCB, 2007). Tailings embankments are susceptible to rapid erosion, cutting down and complete breaching (Toland, 1977). The creation of artificial tailings ponds creates environmental problems of air and water pollution, deforestation and has impacts on agriculture and forestry. Of particular concern is direct discharge of tailings into rivers. Another cause of surface water pollution is the discharge of supernatant effluent into water courses.

In certain mines where ores have high sulfur content, drainage from mine workings and waste heaps can become highly acidic and can contain high concentrations of dissolved heavy metals. This acid mine drainage (AMD) can have a pH of 3 or lower; sulphate levels of 800–1,800 milligrams per litre (mg/l) depending on the contents of the ore. Effluent from tailings ponds may contain concentrations of chromium of several milligrams per liter, chemicals used in flotation and other metal concentration processes could create toxicity problems (World Bank Group, 1998). In the sedimentary deposit mining areas the water table and aquifers are damaged and thus the availability of water from these sources reduces. Tailings must be managed to optimize human safety and environmental protection that is the reason why intensive research and development efforts are being intensified in finding cost-effective solutions in utilizing these industrial wastes.

2.3 Soil Stabilization

Soil stabilization is the alteration of one or more soil properties, by mechanical or chemical means, to create an improved soil material possessing the desired engineering properties. Earlier, soil improvement has been in the qualitative sense only, but more recently, it has also become associated with quantitative values (compressive strength, shearing strength, load bearing quality, adsorption softening and reduction in strength) of strength and durability, which are related to performance (Amu et al., 2005). Soils may be stabilized to increase strength and durability or to prevent erosion and dust generation. Soil stabilization deals with the physical, physico-chemical and chemical methods to

make the stabilized soil to serve its purpose as pavement component material (Koteswara, 2011).

According to Johnson et al. (1988) stabilization infers improvement in both strength and durability. Osinubi and Katte (1991) referred to soil stabilization as the alteration or control of any soil property. It covers not only the increase or decrease of any soil property, but also the variation of any property with changes in environmental condition, namely moisture or pressure.

Primarily, the objectives of stabilization are to improve soil strength, to decrease permeability and water absorption and to improve bearing capacity and durability under cyclical conditions such varying moisture content (Akinmade, 2008).

Soil stabilization has been used in the building of roads, aircraft runways, earth dams and embankment in erosion control (Diamond, 1975; Kawamura and Diamond, 1975) and in reduction of frost heaving.

2.3.1 Mechanical stabilization

This is the process of altering soil properties by changing the gradation through mixing with other soils, densifying the soils using compaction energies, or undercutting the existing soils and replacing them with granular material. In the field, hand-operated vibrating plates and motorized vibratory rollers of various sizes are very efficient in compacting sand and gravelly soils. Large falling weights have been used to dynamically compact loose granular fills (Markwick, 1944).

The objective of mechanical compaction is the improvement of the engineering properties of the soil mass, and the several advantages which are obtained through compaction are as follows (O' Flaherty, 1988):

- i. Reduction in settlement due to reduced void ratio
- ii. Increase in soil strength
- iii. Reduction in shrinkage.

2.3.2 Chemical stabilization

Soil stabilization using chemical admixtures is the oldest and most widespread method of ground improvement. Chemical stabilization is mixing of soil with one of or a combination of admixtures of powder, slurry, or liquid for the general objectives of improving or controlling its volume stability, strength and stress-strain behavior, permeability, and durability (Winterkorn and Pamukçu, 1990).

Traditional stabilizers such as Portland cement, lime and bitumen are used to stabilize soil. However, there are a variety of non-traditional additives available from the commercial sector such as polymer emulsions, acids, lignin derivatives, enzymes, tree resin emulsions, and silicates.

Inorganic salts such as sodium chloride and calcium chloride have long been used in stabilization. Their chief function is to reduce plasticity and facilitate densification (Gillot, 1987; Yamanouchi, 1975; Habercom, 1978; Balogun, 1991).

2.3.2.1 Cement stabilization

Soil which is stabilized with cement is known as cement-soil. The chemical reaction between cement and soil during hydration process will produce binding force.

Cement stabilization is suitable for inorganic soil (Bergado et al., 1996). However, high early strength cement is more effective than the Portland cement (Hammond, 1961).

The Portland Cement Association (1970) has indicated that nearly all types of soils can be stabilized with cement. In general, gravels require about 10 % by weight of cement, sand requires about 7 to 10 %; silts about 12 to 15 % and clays about 12 to 20 % by weight of cement (Gillot, 1987). When soils are sandy, mixing of cement and soil can be carried out at or slightly about optimum moisture content but with clayey soils mixing is most readily achieved with moisture slightly below optimum (Akinmade, 2008).

2.3.2.2 Lime stabilization

Lime reacts with medium, moderately fine and fine-grained soils to produce decreased plasticity, increased workability, reduced swelling, and increased strength. The main reactions include cation exchange, flocculation and pozzolanic reactions (Nelson and Miller, 1992).

Eades and Grim (1960) found that there exists a chemical reaction between lime and pure clay minerals (kaolinite, illite and montmorillonite) with accompanying increase in bearing value. The quantity of lime needed to effectively treat a soil to develop increased strength varies with the type of clay mineral present. Akawwi and Al-Kharabsheh (2002) reported that the swelling and shrinkage potential of soils are affected by mineralogical constituents and surrounding environment.

The optimum amount of lime for maximum strength gain in stabilizing soil with lime according to Eades and Grim (1960) is 4 - 6 % for kaolinite, about 8 % for illite and

montmorillonite. Ola (1978) reported a linear relationship between the strength of lime – stabilized black cotton soil and up to 10 % lime content.

2.3.2.3 Bitumen stabilization

This method enhances the strength of the soil by making it waterproof, forms binding among the soil particles and maintain low moisture content of soil. Bitumen stabilization of any soil can only be feasible if the plasticity index of the soil lies between 6 and 10 %, if otherwise; it may become difficult to stabilize such soils with bitumen, due to the non-pulverizing of the soil (Yoder and Witczak, 1975). Gillot, (1987), Osinubi and Bajeh (1994) as well as Osinubi (2000b, 2001b) reported that bituminous soil stabilization has been most successfully employed in the stabilization of non-cohesive or mildly cohesive soils particularly in warm dry climates where the soil has low moisture content.

2.3.2.4 Agricultural and/or industrial waste stabilization

Previous researches have revealed that the soils could be stabilized effectively using bitumen, lime or cement. Balogun (1991) reported that stabilization of black cotton soil, with lime for example, was not adequate to meet the requirements of the conventional specification for use of the soil in road and highway construction. Similarly, Ibrahim (1983) found that high percentage of cement would be required to stabilize black cotton soil effectively.

The rising cost of conventional soil stabilizers coupled with the need to reduce the cost of waste disposal as well as the need for the economical utilization of industrial and agricultural waste have prompted an investigation into the stabilizing potential of wastes

for beneficial engineering purposes. Fly ash is one of the most plentiful and industrial by-products. It is generated in vast quantities as a by-product of burning coal at electric power plants (Senol et al., 2006).

Fly ash generated by coal combustion based power plants typically fall within the ASTM fly ash classes C and F (Reyes and Pando, 2007). Yudhbir and Honjo (1991) stated that the pozzolanic fly ashes can be advantageously made use of to improve the geotechnical properties of black cotton soils.

Studies have been carried out on the beneficial use of agricultural and industrial waste for construction purposes in the Department of Civil Engineering, Ahmadu Bello University, Zaria. Akinmade (2008) and Osinubi et al. (2009b; 2011) reported that locust bean waste ash has a good potential in improving some of the geotechnical properties of the soil.

Osinubi and Stephen (2005; 2006a,b; 2007), Osinubi and Ijimdiya (2009), Osinubi and Mustapha (2005; 2008), Osinubi and Eberemu (2006), Osinubi et al., (2007a,b; 2009a,b) focused on the use of bagasse ash as possible stabilizers/admixtures for the stabilization of expansive soils. Stephen (2006) studied the potential of bagasse ash as stabilizer on black cotton soil, while Moses (2006) and Osinubi et al. (2008a, b) admixed bagasse ash with lime and cement in stabilizing black cotton soil.

Sayah (1993) and Zaman et al. (1992) reported the effectiveness of cement kiln dust in stabilizing highly expansive clay soils. The use of cement kiln dust in stabilization of clays has been shown to improve the unconfined compressive strength and reduce the plasticity index using dust with low loss on ignition (LOI). On the other hand, adding

cement kiln dust with high LOI resulted in relatively lower unconfined compressive strengths and higher plasticity indices (Bhatty et al., 1996).

2.4 Pozzolanas

Pozzolans are defined as siliceous and aluminous materials which themselves possess little or no cementitious value but will, in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties (Robert, 1993).

2.4.1 Properties of pozzolanas

The chemical composition of pozzolanas can be roughly summarized as follows:

Silica + Alumina + Iron Oxide – Not less than 70 percent

Other Oxides and Alkalis – Not more than 15 percent

Loss on ignition – Not more than 15 percent

The ASTM C618 – 78 specifications for pozzolanas is given in Table 2.1

Table 2.1: Properties of pozzolanas

<u>Property</u>	<u>Class N</u>	<u>Class F</u>	<u>Class C</u>

2.4.2 Fineness of pozzolanas

An essential physical property of a cementing material that affects its affinity for water is its fineness. The activity of pozzolanas is increased by fine grinding. ASTM C618-78 specification requires that the percentage passing sieve No. 200 \geq 85% (Lea, 1956, Smith, 1992).

CHAPTER THREE
MATERIALS AND METHODS

3.1 Materials

3.1.1 Black cotton soil

The soil sample used in this study was obtained near Baure village in Deba Local Government Area (LGA) of Gombe State. It was collected as disturbed sample, excavated from depth not less than 0.5 m so as to avoid any organic material. The samples were packaged in sealed plastic bags for use in laboratory. The collected soil sample was air-dried and pulverized into particles passing BS No. 4 (4.75 mm aperture) sieve before laboratory tests were carried out.

Morin (1971) reported that the Lake Chad Basin is the only extensive lacustrine deposit of black cotton soil in Africa. The black cotton soils of north eastern Nigeria were laid during the tertiary and quaternary periods of the Chad formation and are composed of a sequence of lacustrine and fluvial clays and sands of Pleistocene age. Figure 3.1 shows the geology of the black cotton soil of the Northern Eastern Nigeria.

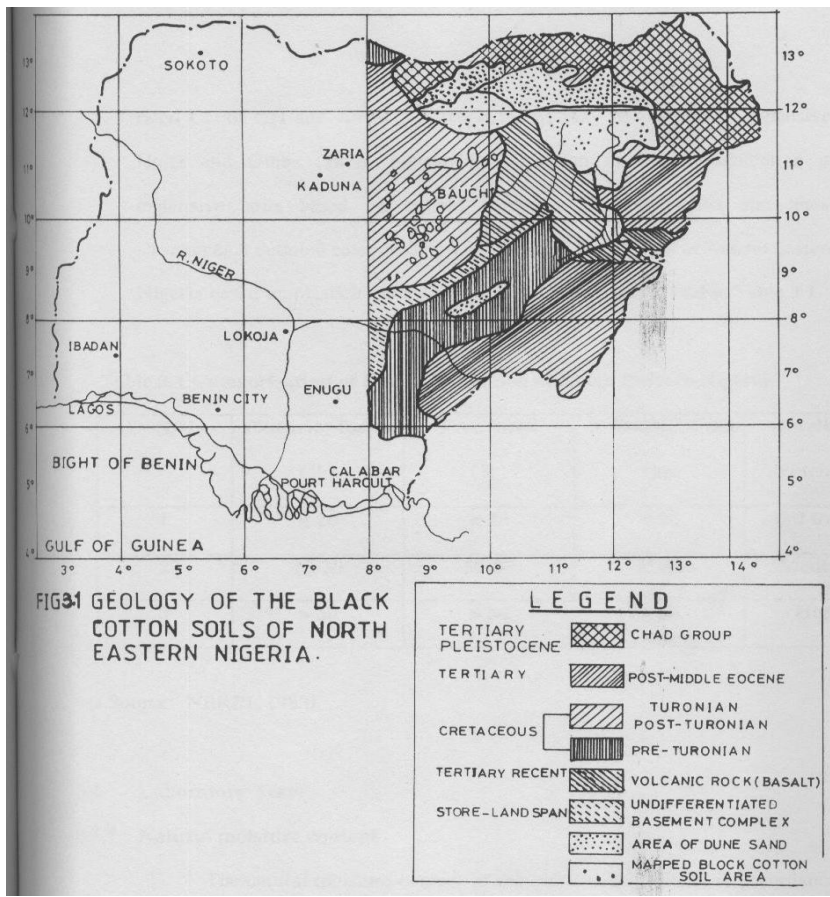

Fig 3.1: Geology of the Black Cotton Soil of the Northern Eastern Nigeria.
(After Ola, 1983)

3.1.2 Iron ore tailing

Iron ore tailing was obtained from the National Iron Ore Mining Company (NIOMCO) waste deposit in Itakpe in Okene Local Government Area of Kogi State of Nigeria. The iron ore tailing sample was passed through BS No. 200 sieve before laboratory tests were carried out.

3.2 Methods

3.2.1 Moisture content

The natural moisture content of the black cotton soil (BCS) was determined in accordance with BS 1377 (1990) Part 2; Test 1(A). A weighing container was cleaned and weighed to the nearest 0.01g. Freshly crumbled sample was loosely placed in the weighed container. The container with sample was weighed to the nearest 0.01g and placed in a thermostatically controlled oven and dried at temperature 105-110°C for 24 hours. The dried sample and container were then weighed to the same accuracy.

Moisture content was determined using the equation

$$W = \frac{M_2 - M_3}{M_3 - M_1} \times 100\% \quad (3.1)$$

W - Moisture content (%)

M₁ - mass of container (g)

M₂ - mass of container + wet soil (g)

M₃ - mass of container + dry soil

Three different tests were carried out from which average natural moisture content was determined.

3.2.2 Specific gravity

The determination of specific gravity was carried out according to BS 1377 (1990) test (B) for fine-grained soils. The density bottle and the stopper were weighed to the nearest 0.01g (m₁). The air-dried soil was transferred into the density bottle, and the bottle, content and the cover were weighed as m₂. Water was then added just enough to cover the soil, the solution is gently stirred to remove any air bubble. The bottle was then completely filled up and covered. The covered bottle was then wiped dry and the whole

weighed to the nearest 0.01g (as m_3). The bottle was subsequently emptied and filled completely with water, wiped dry and weighed to the nearest 0.01g (m_4). The specific gravity is calculated using eqn. (3.2)

$$G_s = \frac{m_2 - m_1}{(m_4 - m_1) - (m_3 - m_1)} \quad (3.2)$$

The procedure was repeated to obtain three values from which the average specific gravity of the modified BCS and IOT were determined.

3.2.3 Particle size distribution

The particle size distribution of the natural soil was determined using both sedimentation analysis and dry sieving of the coarse fraction as specified by BS 1377 (1990) for cohesive soils. The soil sample (200 g) was soaked for 24 hours and washed through BS No. 200 sieve. The materials retained was oven-dried for 24 hours and sieved by agitating it through a range of sieves from sieves No. 7 or 2.4 mm sieve and downwards. The mixture that passes through sieve No. 200 was poured into a 1000 ml measuring cylinder then 25 ml of sodium hexametaphosphate (commercial grade) was added and stirred thoroughly, then hydrometer is immerse gently and readings were taken at intervals stipulated by BS 1377; 1990 Part 2.

3.2.4 Atterberg limits

The Atterberg limits test included the determination of liquid limits, plastic limits and plasticity indices of the natural and modified soil samples. They were also conducted in accordance with Test 1(A) B S 1377 (1990) Part 2 for the natural soil and BS 1924 (1990) for the stabilized soils.

3.2.4.1 Liquid limit

Test 1(A) B.S 1377 (1990) describes the procedure for the determination of liquid limit test of a soil which was adopted for this work. In this test, 200 g of the sample material passing BS No. 40 sieve (425 μ m aperture) was placed on a clean glass plate. The soil was thoroughly mixed with water on this flat glass plate, using palette knife and spatula to form a homogenous paste. A proportion of the paste was placed in Casagrande apparatus and level parallel to the base of the chip and divided by drawing the grooving tool through the paste along diameter passing the centre of the hinge. The crank was turned to lift-drop the cup at the rate of 2 revs per second, noting the number of blows (falls) that would make the bottom two parts of the groove come together. . The liquid limit tests were determined at various moisture contents from drier states to the wetter states. The moisture content was plotted against the respective number of blows on the semi logarithm paper. The liquid limit was deduced as the moisture content corresponding to 25 blows.

3.2.4.2 Plastic limit

A portion of the soil/soil-IOT mixes used for the liquid limit test was retained for the determination of plastic limit. A small portion of the soil sample was put on a flat glass plate and mixed thoroughly enough to be shaped into a small ball. The ball was then moulded between fingers and then rolled on the glass plate with palm of hand into thread of about 3mm diameter when the thread crumbles by shearing. The crumbled threads

were immediately put in weighing pan for moisture content determination. The same test was performed for each of the modified soils.

3.2.4.3 Plasticity index

Having determined the values of the liquid limit and the plastic limit of the soil, plasticity

Indices of the natural and modified soil samples were derived using equation

$$\text{PI} = \text{LL} - \text{PL} \quad (3.3)$$

where,

PI = Plasticity Index

LL= Liquid Limit

PL= Plasticity Limit

3.2.5 Linear shrinkage

The test was performed according to BS 1377 (1990), Test 5, by mixing 125 g of soil passing sieve with 425 µm aperture with water to obtain a homogenous paste. Water mixed with the soil sample was in the same amount as the moisture content corresponding to the liquid limit. The sample was put in shrinkage mould and vibrated gently in order to expel trapped air in the mixture. The soil in the mould was levelled using spatula and then air dried at 60⁰C until the soil shrinks clear off the mould before oven-drying at 105 to 110⁰C to establish a clear and complete shrinkage. After cooling, the sample length was measured using ruler. The linear shrinkage was determined from the equation:

$$\text{Linear Shrinkage} = \frac{(\text{Initial length} - \text{Dried length})}{\text{Initial Length}} \times 100 \% \quad (3.4)$$

This test was carried out for all the soil samples considered.

3.2.6 Free swell

This test was carried out according to United State Bureau of Reclamation (USBR) method (Holtz and Gibbs, 1959). Some 10 g of soil passing sieve with aperture 425 µm was oven dried and allowed to cool in a desiccator. The sample was then slowly poured into 100 cc measuring cylinder to which water was added to the 100 cc mark. The content was then shaken to obtain a homogenous mixture and should be allowed to settle for at least 24 hours before the final level was recorded. Free swell was determined from the equation:

$$\text{Free Swell} = \frac{\text{Final Volume} - \text{Initial Volume}}{\text{Initial Volume}} \times 100\% \quad (3.5)$$

3.2.7 Cation exchange capacity

The test was carried out in accordance with the procedures given by International Soil and Reference Information Center, ISRIC (1998). Some quantity of the natural soil was sieved through the 2 mm screen and 10g of the sieved sample was put into a 100 ml plastic beaker. About 40 ml of ammonium acetate (1N at pH7) was added and stirred using a glass rod and left over night. The sample was then filtered with a light suction using a 55 mm Butcher funnel. The soil was leached with 250 ml of Ammonium acetate (NH_4Ac) until no test for calcium could be obtained in the effluent solution. To test for calcium, diluted Sodium hydroxide (NaOH), few drops of each of 1N NH_4Cl and 10 % ammonium oxalate were added to 10 ml of the leachate in a test tube and heated to near boiling point. The presence of calcium was indicated by a white precipitate or turbidity. As long as calcium was detected, the process was repeated until there was no trace of it.

The calcium-free soil was then leached with neutral 1N ammonium chloride NH_4Cl four times and once with 0.25 N of the acid. The electrolyte was then washed out using 150-200 ml of isopropyl alcohol.

Chloride in the leachate was tested for using silver nitrate (0.1N AgNO_3) till its trace was negligible, and the soil was left to drain thoroughly. A 10% percent acidified NaCl was added little by little to the ammonium saturated soil until 250 ml had passed through the sample, allowing each portion to pass through the sample before adding the next portion. The leachate was transferred in quantities to flask for titration. To it, 25 ml of 1N NaOH was added, and 60 ml of the solution distilled into 50mL of 2% H_3BO_3 . Ten drops of bromocresol green-mythel was added. The colour changed from bluish green to pink at the end of the titration. Blank titration was run on the reagents to correct titration figure for the reagents and the milliequivalents of ammonium in 100g of soil was calculated. The NH_4 -borate was titrated with a standard acid 0.1N HCl in the blank titration. The cation exchange capacity was calculated using eq. (3.6):

$$\frac{(\text{Titre} - B) * NA * 100}{\text{weight of soil}} \quad (3.6)$$

where

B = Blank

NA = Normality of acid

This same procedure was then repeated for each of the sample treated with IOT.

3.2.8 Compaction

Compaction tests on the soil samples were carried out in accordance with BS 1377 (1990) Part 4:3:3 using the British Standard light (BSL) and British Standard heavy (BSH) energies, as well as West African Standard (WAS) described in Nigerian General Specifications (1997). For the BSL, 3 kg of soil sample was thoroughly mixed with 8 % of water (and the water is added at 8 % for each of the compactions). The wet soil was then placed in 1000 mm³ mould and compacted in three equal layers; each layer receiving 27 blows of 2.5 kg rammer, falling through a height of 300 mm. At the end of the compaction, extension collar on the mould was removed and the top of the soil trimmed to level by means of a straight edge. The weight of the mould and the soil sample were measured. The weight of the mould and base had earlier been measured.

In the case of the BSH compactor, test mould of the same capacity was filled in five layers and alternately compacted with 4.5kg rammer falling from 300mm up to 27 blows per layer. The same procedure was followed to determine moisture content. The WAS compactive, effort was derived from a 4.5 kg rammer falling through 300 mm height, 10 times on five layers of the soil and trimmed to level with the mould.

3.2.8.1 Maximum dry density

The bulk and dry density in (Mg/m³) was obtained for each of the soil samples using equation:

$$\rho = \frac{m_2 - m_1}{1000} \quad (3.7)$$

The dry density was also calculated using the equation:

$$\rho_d = 100\rho/(100 + w) \quad (3.8)$$

where,

ρ - Bulk density (Mg/m^3)

m_1 - Mass of empty mould and base (g)

m_2 - Mass of mould, soil and base (g)

W - Moisture content (%)

ρ_d - Dry density.

The values of the dry densities as obtained from eqn. (3.8) were plotted against their respective moisture contents and the maximum dry density (MDD) was deduced as the maximum point on the resultant curves

3.2.8.2 Optimum moisture content

Optimum moisture content, the amount of water content corresponding to maximum dry density of the sample read from the MDD/moisture content graph.

3.2.9 Unconfined compressive strength

The unconfined compressive strength (UCS) tests were performed on the soil samples according to BS 1377; 1990 Part 7 using the British Standard light (BSL), West African Standard (WAS) and British Standard heavy (BSH) energy levels. The natural air dried soil sample/the stabilized soil samples were compacted in 1000 cm^3 moulds at their respective optimum moisture contents using the three energy levels described earlier. The predetermined quantities of soil, iron ore tailing and water obtained from moisture-density relationship were thoroughly mixed. Three samples for various percentages of soil iron ore tailing mixes were extruded from the moulds and trimmed into a cylindrical specimen of 38.1 mm diameter and 76.2 mm length. Each specimen was cured by sealing

in a polythene bag for 7, 14 and 28 days with another set of samples cured for 7 days and soaked in water for another 7 day for durability assessment.

At the elapsed day of curing, the specimens were then placed centrally on the lower platen of a compression testing machine and a compressive force was applied to the specimen with a strain control at 0.10 % mm. Record was taken simultaneously of the axial deformation and the axial force at regular interval until failure of the sample occurred. The UCS of the sample was determined at the point on the stress–strain curve at which failure occurred. The UCS was calculated from the following equation:

$$\text{Compressive strength} = \frac{\text{Failure load}}{\text{Surface Area of Specimen}} \quad (3.9)$$

3.2.10 California bearing ratio

The California bearing ratio (CBR) test was carried out as a measure of strength of the natural and stabilized soil. The aim of the CBR test was to determine the relationship between force and penetration. The CBR is expressed by the force exerted by the plunger by the depth of its penetration into the specimen. The tests were carried out in conformity with the B.S. 1377 (1990), B.S. 1924 (1990) and the Nigerian General Specifications (1997).

For the British Standard light (standard Proctor) compaction, 5 kg of the natural or stabilised soil sample were mixed at respective optimum moisture content in 2360 cm³ mould, at the three compactive efforts. The mixture was then compacted in 3 equal layers in the CBR mould, with 62 blows of the 2.5 kg rammer was applied to each layer for BSL. For the WAS, the samples were compacted in five layers with 25 blows from the 4.5 kg rammer and for the BSH, the sample received 62 blows in 5 layers from the 4.5 kg

rammer. The extension collar was removed and the top of the compacted sample trimmed carefully and waxed. The samples were kept in the humidity room at a temperature of 20 ± 2°C and 100 % relative humidity for 6 days. Durability assessment of CBR specimens entailed immersion of the 6 days cured specimens in water for about 24 hours before testing; this is in accordance with the Nigerian General Specifications (1997). The specimens were then transferred to the CBR testing machine. The plunger was then made to penetrate the specimen at a uniform rate. The dial reading indicating, forces were taken each at 0.25 mm interval of penetration until the maximum of 7.50 mm was attained or alternatively until failure was reached. The bottom of the specimens was also tested in like manner. The CBR curves were plotted using the values obtained from the tests. The CBR was calculated at the penetration of 2.50 mm and 5.0 mm as:

$$\text{CBR} = \frac{\text{Measured load}}{\text{Standard load}} \times 100\% \quad (3.10)$$

where standard load = 13.24 kN of 2.5 mm penetration

= 19.96 kN of 5.0 mm penetration

However, where the values are within 10 % of each other, the mean value of the two readings was considered, otherwise the higher value was recorded as the CBR of the specimen

3.2.11 Durability

The durability assessment (under adverse field conditions) of the soil sample was determined by resistance to loss in strength when immersed in water. It was expressed as

the ratio of UCS of the specimen cured for 7 days and soaked for another 7 days to the UCS of the specimen cured for 14 days:

$$\text{Resistance to loss in strength (\%)} = \frac{\text{UCS}(7 \text{ day cured} + 7 \text{ day soaked})}{\text{UCS}(14 \text{ day cured})} \times 100\% \quad (3.11)$$

3.2.12 Analysis of variance

The problem of analyzing quality of estimated regression line can be handled by analysis of variance (ANOVA). This procedure subdivides the total variations in independent variables into meaningful components that are observed and treated in a systematic manner. Let our experimental data be in the form (x_i, y_i) in n-numbers of experiments and the regression line is estimated then (Montgomery, 2001)

$$S_{yy} = bS_{xy} + SSE \quad (3.12)$$

where,

b = slope of underlying straight line of relationship.

An alternative and perhaps more informative formulation is

$$\sum_{i=1}^n (y_i - \bar{y})^2 = \sum_{i=1}^n (\hat{y}_i - \bar{y})^2 + \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad (3.13)$$

By using the above formula, the total experimental data are partitioned into two components with corrected sum of squares of y that makes the best fit line of regression to establish whether results of experiments fall within acceptable limits or confidence level.

This partitioning shall be represented symbolically as:

$$SST = SSR + SSE \quad (3.14)$$

where,

SSR = the regression sum of squares which reflects variation in the parallel values of the model i.e. a postulated straight line.

SSE = the second component, the sum of squares of errors, reflecting variation about the regression lines.

Suppose that we have to test the following hypothesis

HQ: $\beta = 0$,

HI: $\beta \neq 0$,

Where the null hypothesis indicates that the model is $\mu_y|x = a$. That means Y results from chance or random fluctuations which are independent of values of x . Under the null hypothesis it can be shown that SSR/σ^2 and SSE/σ^2 are values of chi-squared variables with 1 and $(n-2)$ degrees of freedom respectively. This implies that SST/σ^2 is also a value of a chi-squared variable with $n-1$ degrees of freedom.

For the above hypothesis testing, let calculate

$$f = \frac{SSR/1}{SSE/(n-2)} = \frac{SSR}{s^2} \quad (3.15)$$

We should note that HQ is rejected as the level of significance, “when the null hypothesis is rejected. That is, when the F-statistic exceed the critical value, $f_{Q,(1,n-2)}$, we conclude that there is a significant amount of variation in the response accounted for by the postulated straight line function. If the F-statistic is smaller we reject, we conclude that the data did not reflect sufficient evidence to support the model postulated”. The computed results from this analysis are presented by means of table of analysis of

variance. It is customary to refer to the various sums of squares divided by their respective degrees of freedom as the mean squares.

3.2.13 Microanalysis

Microanalysis of specimens treated with optimal concentration of IOT was carried out using a scanning electron microscope (SEM) to examine the structural arrangement. The natural soil and soil sample that gave the optimum blend for the BSL compactive effort were prepared and cured for 7 days and 28 days then a section of it was viewed using the scanned electron microscope.

CHAPTER FOUR

RESULTS AND DISCUSSION

4.1 Properties of Materials Used in the Study

4.1.1 Black cotton soil

Preliminary tests conducted on the natural properties of the black cotton soil revealed that the soil has low moisture content of 15.2 %. The index properties are summarized in Table 4.1. The particle size distribution is shown in Fig. 4.1. The soil belongs to the CH group in the Unified Soil Classification System (ASTM, 1992) or A-7-6 (13) soil group of the AASHTO soil classification system (AASHTO, 1986). The soil is greyish black in colour (from wet to dry states) with a liquid limit of 64.5 %, plastic limit of 25 % and plasticity index of 39.5 %.

The soil has a free swell of about 85 %, soaked California bear ratio (CBR) values of 3, 4 and 5 % for British Standard light, West African Standard and British Standard heavy compaction energies, respectively, and unconfined compressive strength (UCS) values of 238.03, 346.98 and 458.37 kN/m² for the three energy levels, respectively. The soil was found to be highly plastic and fell below the standard recommendation for most geotechnical construction works especially highway construction in agreement with the findings reported by Butches and Sailie (1984) as well as Osinubi and Medubi (1997a). Detailed test results are given in Tables A4.2 – A4.11 in Appendix A.

4.1.2 Iron ore tailing

The specific gravity of the iron ore tailing (IOT) was found to be 3.76. The high content of silicon and iron oxides in IOT provided the required improvement in the stabilization process. Table 4.3 shows the summary of the oxide composition of IOT

Table 4.2: Oxide composition of iron ore tailing

4.1.3 Cation exchange capacity

The primary factor that determines cation exchange capacity (CEC) is the clay and organic matter of the soil (Hamza, 2008). The variation of cation exchange capacity of black cotton soil with iron ore tailing (IOT) content is shown in Fig. 4.2. Cation exchange capacity increased from 0 to 10% IOT content and then reduced with higher IOT content up to 16%. The peak value of 42.2 Cmol/kg at 10% IOT might be considered as optimum for the black cotton soil – iron ore tailing mixture.

Fig. 4.2: Variation of cation exchange capacity of black cotton soil with iron ore tailing content

The increase in CEC of the black cotton soil was probably due to the increased pH of the soil by the IOT that has a little calcium hydroxide content which supplied free Ca^{2+}

required for the cation exchange between the clay mineral particles and additive. The detailed results are given in Table A4.6 of Appendix A.

An analysis of variance (ANOVA) test on the CEC result shows that the effect of IOT on black cotton soil was statistically significant ($F_{CAL} = 238.52 > F_{CRIT} = 4.49$). The detailed test results are given in Table B4.1 of Appendix B.

4.2 Sieve Analysis

4.2.2 Wet sieving

The particle size distribution from hydrometer test for the natural and treated black cotton soil samples are shown in Fig. 4.3. A reduction in the percentage of fines with increasing IOT content can be noticed. It was observed that there was a slight reduction in the silt fraction of the soil from 14.33 % for the natural soil to 0 % at 16 % IOT content. This reduction may not be unconnected with the agglomeration and flocculation of the clay particles and a result of ion exchange at the surface of the clay particles; as the excess Ca^{2+} in IOT reacted with the lower valence metallic ions in the clay structure. Detailed test results are given in Table A4.4(a) of Appendix A.

Fig. 4.3: Particle size distribution curves for black cotton soil – iron ore tailing mixtures (Wet sieving)

4.2.3 Dry Sieving

4.2.3.1 Using optimum moisture content from British Standard light compaction

The particle size distribution of the modified soil using optimum moisture content from BSL compaction is shown in Fig. 4.4. A reduction in the percentage of fines with increasing IOT content was noticed.

The reduction in clay content was due to the hydration of IOT which acted as a nucleus to which soil particles adhered. With increase in IOT content the quantity of free silt and clay progressively reduced and coarser materials were formed in agreement with Kedzi (1979), Osinubi (1995) and Sani (2012). Detailed test results are given in Table A4.4 (b) of Appendix A.

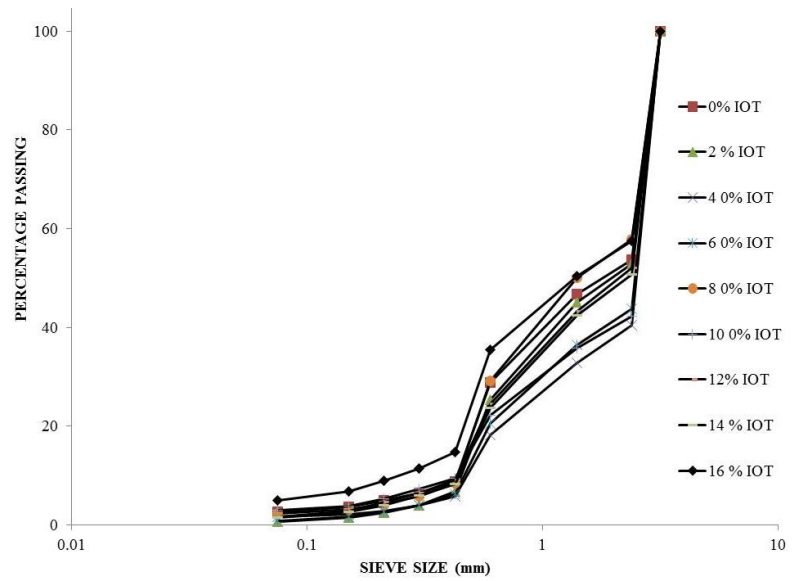

Fig. 4.4: Particle size distribution curves for black cotton soil – iron ore tailing mixtures (BSL compaction)

4.2.3.2 Using optimum moisture content from West African Standard compaction

The particle size distribution of the modified soil using optimum moisture content from WAS compaction is shown in Fig. 4.4. A reduction in the percentage of fines with increasing IOT content was noticed.

The reduction in clay content was due to the hydration of IOT which acted as a nucleus to which soil particles adhered. With increase in IOT content the quantity of free silt and clay progressively reduced and coarser materials were formed in agreement with Kedzi (1979), Osinubi (1995) and Sani (2012). Detailed test results are given in Table A4.4 (b) of Appendix A.

Fig. 4.5: Particle size distribution curves for black cotton soil – iron ore tailing mixtures (WAS compaction)

4.2.3.3 Using optimum moisture content from British Standard heavy compaction

The particle size distribution for BSH compaction are shown in Fig. 4.6. There was a reduction in the percentage of fines with increased in IOT content as shown on the curves. A little change is noticed in the coarser sizes. The IOT content caused the soil - IOT mixture to flocculate and agglomerate more and hence the mixture got coarser enabling the clay particle to form pseudo silt sizes. The results are consistent with the findings reported by Osula (1991), Obeahon (1993) and Oyelakin (2011). Detailed test results are given in Table A4.4 (d) of Appendix A.

Fig. 4.6: Particle size distribution curves for black cotton soil – iron ore tailing mixtures (BSH compaction)

4.3 Atterberg Limits

4.3.1 Liquid limit

The variation of liquid limit (LL) of the black cotton soil with iron ore tailing content is shown in Fig.4.7. An initial increase in liquid limit with addition of IOT was observed. The liquid limit increased from 64.5 % for the natural black cotton soil to 71 % at 2% IOT content and thereafter steadily decreased to 59.9 % at 16% IOT content. The initial increase in the liquid limit value could be due to pozzolanic substances in the IOT that required more amount of water for hydration to go to completion while the reduction might be the result of agglomeration and flocculation of the clay particles. Detailed test results are given in Table A4.5 of Appendix A.

Fig. 4.7: Variation of Atterberg limits of black cotton soil with iron ore tailing content

The analysis of variance (ANOVA) test results (see Table 4.3) shows that the effect of the IOT on the liquid limit of black cotton soil was statistically significant ($F_{CAL} = 693.0489 > F_{CRIT} = 4.49$). Detailed test results are given in Table B4.2 (a) of Appendix B.

Table 4.3 : Results of one - way analysis of variance for Atterberg limits of black cotton soil - iron ore tailing mixtures

<u>Property</u>	<u>Source of variation</u>	<u>Degree of freedom</u>	<u>F_{cal}</u>	<u>P_{value}</u>	<u>F_{crit}</u>	<u>Remark</u>
Liquid	IOT	1	693.05	1.33E-14	4.49	$F_{CAL} > F_{CRIT}$.

<u>Limit</u>						<u>Significant effect</u>
<u>Plastic Limit</u>	<u>IOT</u>	<u>1</u>	<u>117.53</u>	<u>8.83E-09</u>	<u>4.49</u>	<u>$F_{CAL} > F_{CRIT}$</u> <u>Significant effect</u>
<u>Plasticity Index</u>	<u>IOT</u>	<u>1</u>	<u>165.37</u>	<u>7.5E-10</u>	<u>4.49</u>	<u>$F_{CAL} > F_{CRIT}$</u> <u>Significant effect</u>
<u>Linear Shrinkage</u>	<u>IOT</u>	<u>1</u>	<u>41.33</u>	<u>8.33E-06</u>	<u>4.49</u>	<u>$F_{CAL} > F_{CRIT}$</u> <u>Significant effect</u>

4.3.2 Plastic limit

The variation of the plastic limit of black cotton soil with iron ore tailing content is shown in Fig. 4.7. Plastic limit increased from a value of 25 % for the natural black cotton soil to a peak value of 34.9 % at 8% IOT content. Thereafter, it reduced with higher IOT content to 27.5 % at 16 % IOT content. This trend is in conformity with the findings reported by Alhassan (2006) and Mustapha (2006). Detailed test results are given in Table A4.5 of Appendix A.

The analysis of variance (ANOVA) test results (see Table 4.3) shows that the effect of IOT on the plastic limit of the treated black cotton soil was statistically significant ($F_{CAL} = 117.43 > F_{CRIT} = 4.49$) Detailed test results are given in Table B4.2(b) of Appendix B.

4.3.3 Plasticity index

The variation of the plasticity index of black cotton soil with iron ore tailing content is shown in Fig. 4.7. There was an initial slight increase in the plasticity index value from 39.5 % for the natural soil to 40.59 % at 2 % IOT content. Thereafter, the value decreased to 42.4 % at 16 % IOT content. Detailed test results are given in Table A4.5 of Appendix A.

The one-way analysis of variance (ANOVA) test results (see Table 4.3) shows that the effect of IOT on the plasticity index of the treated black cotton soil was statistically significant ($F_{CAL} = 165.36 > F_{CRIT} = 4.49$). Detailed test results are given in Table A4.2 (c) of Appendix B.

4.3.4 Linear shrinkage

The variation of the linear shrinkage of black cotton soil with iron ore tailing content is shown in Fig. 4.7. Generally, the linear shrinkage of black cotton soil reduced with higher IOT treatments from 27.14 % for the natural soil to 16.2 % at 16 % IOT content. This trend is in conformity with the findings reported by Ola (1991), Osinubi (1995, 1999) and Azige (2012). Detailed test results are given in Table A4.5 of Appendix A.

The analysis of variance (ANOVA) test results (see Table 4.3) shows that the effect of IOT on the linear shrinkage of black cotton soil was statistically significant ($F_{CAL} = 41.32 > F_{CRIT} = 4.49$). Detailed test results are given in Table A4.2(d) of Appendix B.

4.4 Compaction Characteristics

4.4.1 Maximum dry density

The variation of the maximum dry density (MDD) of black cotton soil with iron ore tailing content for the three compactive efforts is shown in Fig. 4.8. The MDD values increased with higher iron ore tailing content and compactive effort.

Fig. 4.8: Variation of maximum dry density of black cotton soil with iron ore tailing content

Maximum dry density values increased from 1.38, 1.52 and 1.59 Mg/m³ for the natural black cotton soil compacted with BSL, WAS and BSH energies, respectively, to 1.53, 1.66 and 1.72 Mg/m³, respectively, at 16 % IOT content. The increase in MDD for the BSL, WAS and BSH compactive efforts is in conformity with the trend of increasing MDD/decreasing OMC. This is as a result of IOT occupying the void within the soil matrix in addition to the flocculation and agglomeration of the clay particle due to exchange of ions (Osinubi, 2000 a; Moses, 2008; Oriola and Moses, 2010). Detailed test results are given in Table A4.7 of Appendix A.

Results of one way analysis of variance for compaction characteristics of black cotton soil – iron ore tailing mixtures are summarised in Table 4.4. The results shows that the effect of IOT on the maximum dry density was statistically significant for BSL ($F_{CAL} = 12.75 > F_{CRIT} = 4.49$), WAS ($F_{CAL} = 12.30 > F_{CRIT} = 4.49$) and BSH ($F_{CAL} = 12.04 > F_{CRIT} = 4.49$) compactions. Detailed test results are given in Table B4.3a - c of Appendix B.

Results of two-way analysis of variance (ANOVA) for compaction characteristics of iron ore tailing-compactive effort are summarised in Table 4.5. The results show that the effect of the iron ore tailing and compactive effort on the maximum dry density was statistically significant ($F_{CAL} = 74.85 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 900.04 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.8 of Appendix B.

Table 4.4: Results of one-way analysis of variance for compaction characteristics of black cotton soil - iron ore tailing mixtures

<u>Property</u>		<u>Source of variation</u>	<u>Degree of freedom</u>	<u>F_{calculated}</u>	<u>P-value</u>	<u>F_{critical}</u>	<u>Remark</u>
<u>BSL</u>	<u>MDD</u>	<u>IOT</u>	<u>1</u>	<u>12.76</u>	<u>0.0025</u>	<u>4.49</u>	<u>$F_{CAL} > F_{CRIT}$, Significant effect</u>

4.4.2 Optimum moisture content

The variation of optimum moisture content of black cotton soil with IOT for BSL, WAS and BSH compactive efforts is shown in Fig. 4.9. Optimum moisture content (OMC) values decreased from 28.5, 18.5 and 11.5 % for the natural black cotton soil compacted with BSL, WAS and BSH energies, respectively, to minimum values of 22.0, 14.0 and 11.5 % at 16, 14 and 14 % IOT contents, respectively.

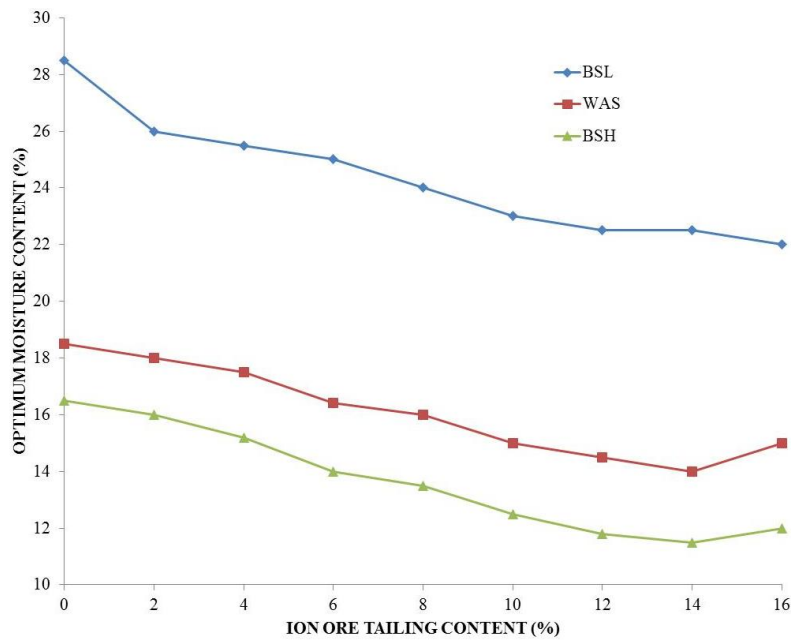

Fig. 4.9: Variation of optimum moisture content of black cotton soil with iron ore tailing content

The decrease in OMC values were probably due to self –desiccation in which all the water was used, resulting in low hydration. When no water movement to or from soil-IOT paste is permitted, the water is used up in the hydration reaction, until too little is left to saturate the solid surfaces and hence the relative humidity within the paste decreases. The process described above might have affected the reaction mechanism of IOT treated black cotton soil (Osinubi and Stephen, 2007, Moses, 2008).

Furthermore, the cause for the reduction in the OMC values can also be explained as follows: the cation exchange between additives and expansive soil decreases the thickness of electric double layer and promotes the flocculation. The flocculation of the

solid particles implies that the water-additives–soil mixtures can be compacted with lower water content, and the optimum water content is reduced (Bose, 2012).

The observed decrease of OMC values with higher compactive efforts was because it was easier to breakdown flocculated aggregates, destroy shear planes and eliminate large pores, at higher compactive efforts (Osinubi, 1999). Detailed test results are given in Table A4.9 of Appendix A.

Results of one way analysis of variance for compaction characteristics of black cotton soil – iron ore tailing mixtures given in Table 4.4 show that the effect of IOT on the optimum moisture content of black cotton soil was statistically significant for BSL ($F_{CAL} = 69.59 > F_{CRIT} = 4.49$), WAS ($F_{CAL} = 18.11 > F_{CRIT} = 4.49$) and BSH ($F_{CAL} = 8.61 > F_{CRIT} = 4.49$) Detailed test results are given in Table B4.4 (c) of Appendix B.

Results of two-way analysis of variance (ANOVA) for compaction characteristics of iron ore tailing-compactive effort are summarised in Table 4.5. The results show that the effect of the iron ore tailing and compactive effort on the optimum moisture content was statistically significant ($F_{CAL} = 54.73 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 1499.89 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.9 of Appendix B.

4.5 Strength Characteristics

4.5.1 Unconfined compressive strength

The main test recommended for use for determining required amount of additive to be used in the stabilization of soils is the unconfined compressive strength

(UCS) test (Singh, 1991). It is an important factor in the evaluation of the design criteria for the use of soil as a pavement material (Ola, 1983).

4.5.1.1 7 days curing period

The UCS of specimens compacted at the energy levels of the BSL, WAS and BSH and cured for 7 days are shown in Fig. 4.10. Generally, UCS values increased with higher compactive effort and IOT content.

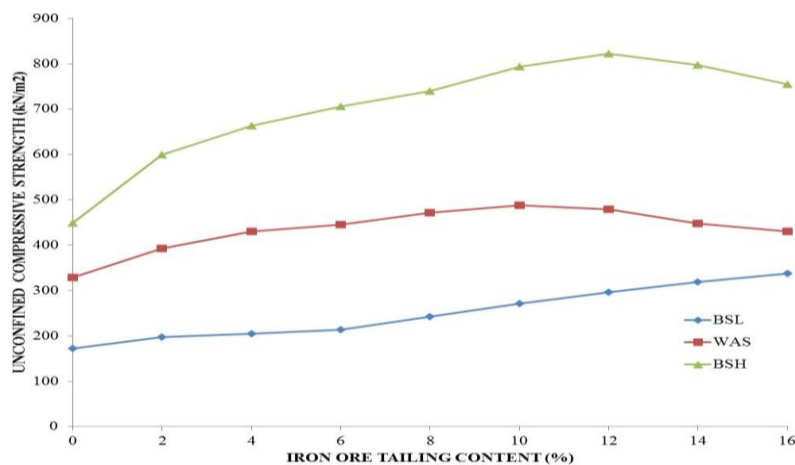

Fig. 4.10 Variation of unconfined compressive strength (7 days curing period) of black cotton soil with iron ore tailing content

For BSL compaction, UCS values increased from 172.59 kN/m² for the natural black cotton soil to 337.77 kN/m² at 16 % IOT. The compaction carried out using WAS energy showed that UCS value increased from 328.36 kN/m² for the natural soil to a peak value of 487.57 kN/m² at 10 % IOT content and thereafter reduced to 429.99 kN/m² at 16 % IOT treatment. With respect to BSH compaction, UCS values increased from 488.83kN/m² for the natural black cotton soil to 821.57kN/m² at 12 % IOT content and thereafter reduced to 754.94kN/m² at 16 % IOT content. The increase in UCS values

could be attributed to ion exchange at the surface of clay particles. The Ca^{2+} in the additives reacted with the lower valence metallic ions in the clay microstructure which resulted in agglomeration and flocculation of the clay particles (Moses and Saminu, 2012). Detailed test results are given in Table A4.9 of Appendix A.

Results of analysis of variance (ANOVA) for strength characteristics of black cotton soil – iron ore tailing mixtures are given in Table 4.6. For BSL, WAS and BSH compactions the results show that the effect of IOT on unconfined compressive strength (7 days curing period) was statistically significant for BSL ($F_{\text{CAL}} = 154.49.39 > F_{\text{CRIT}} = 4.49$), WAS ($F_{\text{CAL}} = 661.26 > F_{\text{CRIT}} = 4.49$) and BSH ($F_{\text{CAL}} = 309.15 > F_{\text{CRIT}} = 4.49$) compactive efforts. Detailed test results are given in Table B4.5 of Appendix B.

Results of two-way analysis of variance (ANOVA) for strength characteristics of iron ore tailing-compactive effort are summarised in Table 4.7. The results show that the effect of the iron ore tailing and compactive effort on the unconfined compressive strength (7 days curing period) was statistically significant ($F_{\text{CAL}} = 6.48 > F_{\text{CRIT}} = 2.59$) for IOT and ($F_{\text{CAL}} = 198.75 > F_{\text{CRIT}} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.10a of Appendix B.

4.5.1.2 14 days curing period

The UCS of specimens compacted at the energy levels of the BSL, WAS and BSH and cured for 14 days are shown in Fig. 4.11. The UCS values increased with higher IOT content and compactive effort.

Fig. 4.11: Variation of unconfined compressive strength (14 days curing period) of black cotton soil with iron ore tailing content

For BSL compaction the UCS values increased from 238.03 kN/m² for natural black cotton soil to 432.16 kN/m² at 16 % IOT. The compaction carried out using WAS and BSH energies showed that UCS increased from 346.98 and 458.37 kN/m² for natural soil to peak values of 478.1 and 789.23 kN/m² , respectively, at 14 % IOT content. Detailed test results are given in Table A4.9(a) of Appendix A.

This increase in compressive strength with curing period can be attributed to time dependent strength gain of the pozzolanas.

Results of analysis of variance (ANOVA) for strength characteristics of black cotton soil – iron ore tailing mixtures are given in Table 4.6. For BSL, WAS and BSH compactions the results show that the effect of IOT on the unconfined compressive

strength (14 days curing period) was statistically significant for BSL ($F_{CAL} = 319.01 > F_{CRIT} = 4.49$, WAS ($F_{CAL} = 781.09 > F_{CRIT} = 4.49$, BSH ($F_{CAL} = 263.99 > F_{CRIT} = 4.49$). Detailed test results are given in Table A4.5 (d, e and f) of the Appendix.

Results of two-way analysis of variance (ANOVA) for strength characteristics of iron ore tailing-compactive effort are summarised in Table 4.7. The results show that the effect of the iron ore tailing and compactive effort on the unconfined compressive strength (14 days curing period) was statistically significant ($F_{CAL} = 9.58 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 125.67 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.10b of Appendix B.

4.5.1.3 28 days curing period

The UCS of specimens compacted at the energy levels of the BSL, WAS and BSH and cured for 28 days are shown in Fig. 4.12. Generally, UCS values increased with higher compactive effort and IOT content.

Fig. 4.12: Variation of unconfined compressive strength (28 days curing period) of black cotton soil with iron ore tailing content

For BSL, WAS and BSH compaction, UCS values for 28 days curing period increased from 273.24, 514.45 and 627.81kN/m² for the natural black cotton soil to 504.91, 1009.31, 947.68 and 1009.31kN/m² respectively at 16 % IOT content.

The increase in strength could be due to the presence of iron oxide (goethite) which dehydrates with time to yield higher strength in agreement with Nixon and Skipp, (1957), Little (1967) and Osinubi (2001a). The trend of increased compressive strength with curing period can also be attributed to time dependent strength gain action of the pozzolanas (Osinubi and Moses, 2013). Detailed test results are given in Table A4.9(c) of the appendix A.

Results of analysis of variance (ANOVA) for strength characteristics of black cotton soil – iron ore tailing mixtures are given in Table 4.6. For BSL, WAS and BSH compactions the results show that the effect of IOT on the unconfined compressive strength (28 days curing period) was statistically significant for BSL ($F_{CAL} = 296.09 > F_{CRIT} = 4.49$), WAS ($F_{CAL} = 228.52 > F_{CRIT} = 4.49$), BSH ($F_{CAL} = 307.22 > F_{CRIT} = 4.49$). Detailed test results are given in Table B4 .5 (g, h and i) of Appendix B.

Results of two-way analysis of variance (ANOVA) for strength characteristics of iron ore tailing-compactive effort are summarised in Table 4.7. The results show that the effect of the iron ore tailing and compactive effort on the unconfined compressive strength (28 days curing period) was statistically significant ($F_{CAL} = 19.62 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 201.08 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.10c of Appendix B.

4.5.1.47 days curing and 7 days soaking periods

The UCS of specimens compacted at the energy levels of the BSL, WAS and BSH and cured for 7 days curing and 7 days soaking periods are shown in Fig 4.13. UCS values increased with higher compactive effort and IOT content.

Fig. 4.13: Variation of unconfined compressive strength (7 days curing + 7 days soaking) of black cotton soil with iron ore tailing content

UCS values for specimens compacted at the energies of the BSL, WAS and BSH, increased from 25.72, 41.08 and 60.02 kN/m² for the natural black cotton soil to peak values of 90.37, 115.14 and 120.03 kN/m² at 10, 12 and 10 % IOT respectively and then reduced to minimum values of 59.70, 78.90 and 97.05 kN/m² at 16 % IOT treatment. It is pertinent to note here that the UCS values for the soaked specimens are too low compared to those obtained for 7 and 14 days curing periods; which is probably due to the ingress of water that resulted in loss of strengths. Detailed test results are given in Table A4.9(d) of Appendix A.

Results of analysis of variance (ANOVA) for strength characteristics of black cotton soil – iron ore tailing mixtures are given in Table 4.6. For BSL, WAS and BSH

compactions the results show that the effect of IOT on the unconfined compressive strength (7 days curing + 7 days soaking periods) was statistically significant for BSL ($F_{CAL} = 48.96 > F_{CRIT} = 4.49$), WAS ($F_{CAL} = 63.27 > F_{CRIT} = 4.49$) and BSH ($F_{CAL} = 171.08 > F_{CRIT} = 4.49$). Detailed test results are given in Table B4.5 (j, k and l) of Appendix B.

Results of two-way analysis of variance (ANOVA) for strength characteristics of iron ore tailing-compactive effort are summarised in Table 4.7. The results show that the effect of the iron ore tailing and compactive effort on the unconfined compressive strength (7 days curing and 7 days soaking periods) was statistically significant ($F_{CAL} = 41.33 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 56.21 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.10d of Appendix B.

4.6 California Bearing Ratio

California bearing ratio (CBR) is an important parameter that indicates the strength and bearing ability of a soil, which will assist the designer in recommending or rejecting the soil as suitable for base or sub-base for a flexible road pavement.

4.6.1 Unsoaked California bearing ratio

The variation of California bearing ratio (unsoaked condition) with iron ore tailing content for specimens compacted at the energy levels of the BSL, WAS and BSH is shown in Fig. 4.14. For BSL, WAS and BSH compactions, unsoaked CBR values increased from 8, 10 and 15 % for the natural black cotton soil to peak values of 29, 20 and 17 % were recorded at 12, 14 and 12 % IOT content, respectively.

Detailed test results are given in Table A4.10(a) of Appendix A.

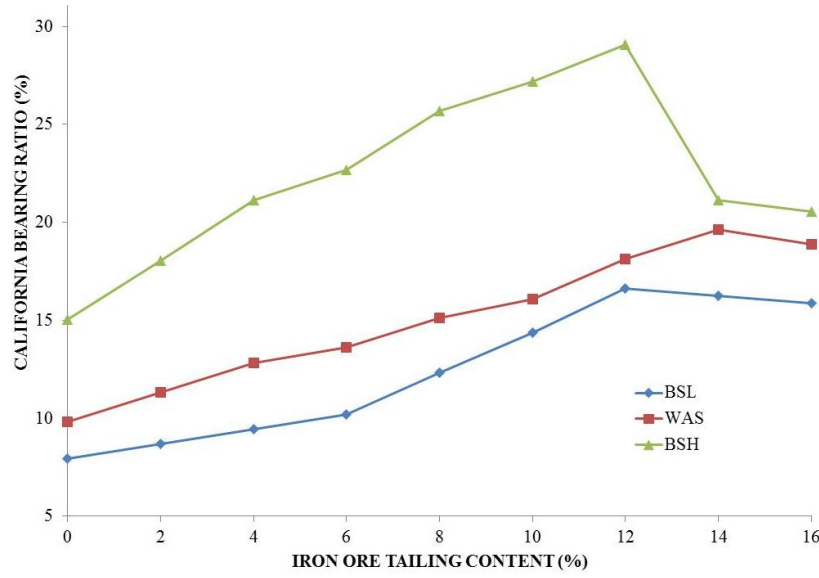

Fig. 4.14: Variation of California bearing ratio (unsoaked condition) with iron ore tailing content

The Nigerian General Specifications (1997) recommends that a CBR value of 180 % should be attained in the laboratory for cement stabilization. However, an unsoaked CBR value of 80 % is required for bases and soaked value of 30 % for sub-bases both when compacted at optimum moisture content and at 100 % West African Standard compaction (Gidigasu and Dogbey, 1980; Gidigasu, 1982; Osinubi, 2001a). The CBR values recorded for the IOT stabilized soil at the three compactive efforts are lower than those prescribed by Nigerian General Specifications (1997). It implies that IOT cannot be used as a 'stand alone' additive.

Results of analysis of variance (ANOVA) for unsoaked CBR of black cotton soil – iron ore tailing mixtures are given in Table 4.8. For WAS and BSH compactions the

results show that the effect of IOT on the unsoaked CBR was statistically significant for WAS ($F_{CAL} = 10.69 > F_{CRIT} = 4.49$) and BSH ($F_{CAL} = 36.88 > F_{CRIT} = 4.49$). Detailed test results are given in Table B4.6(a, b and c) of Appendix B.

Results of two-way analysis of variance (ANOVA) for California bearing ratio of iron ore tailing-compactive effort are summarised in Table 4.9. The results show that the effect of the iron ore tailing and compactive effort on the unsoaked CBR was statistically significant ($F_{CAL} = 7.75 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 52.67 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.11 of Appendix B.

Table 4.8: Results of one-way analysis of variance for California bearing ratio of black cotton soil-iron ore tailing mixtures

Property		Source of Variation	Degree of Freedom	F_{CAL}	P-value	F_{CRIT}	Remark
BSL	Unsoaked	IOT	1	4.16	0.0582	4.49	No Significant effect
	Soaked	IOT	1	4.10	0.0598	4.49	No Significant effect
WAS	Unsoaked	IOT	1	10.70	0.0048	4.49	Significant effect
	Soaked	IOT	1	0.79	0.3863	4.49	No Significant effect
BSH	Unsoaked	IOT	1	36.88	1.61E-05	4.49	Significant effect
	Soaked	IOT	1	0.17	0.6857	4.49	No Significant effect

<u>SOAKED CBR</u>	<u>IOT</u>	<u>8</u>	<u>9.516362</u>	<u>8.27E-05</u>	<u>2.591096</u>	$\frac{F_{CAL}}{F_{CRIT}}$, Significant effect
	<u>COMPACTIVE EFFORT</u>	<u>2</u>	<u>65.63648</u>	<u>1.94E-08</u>	<u>3.633723</u>	$\frac{F_{CAL}}{F_{CRIT}}$, Significant effect

4.6.2 Soaked California bearing ratio

The variation of California bearing ratio (24 hours soaking period) with iron ore tailing content for specimens compacted at the energy levels of the BSL, WAS and BSH is shown in Fig. 4.15. It was observed that with higher IOT content and

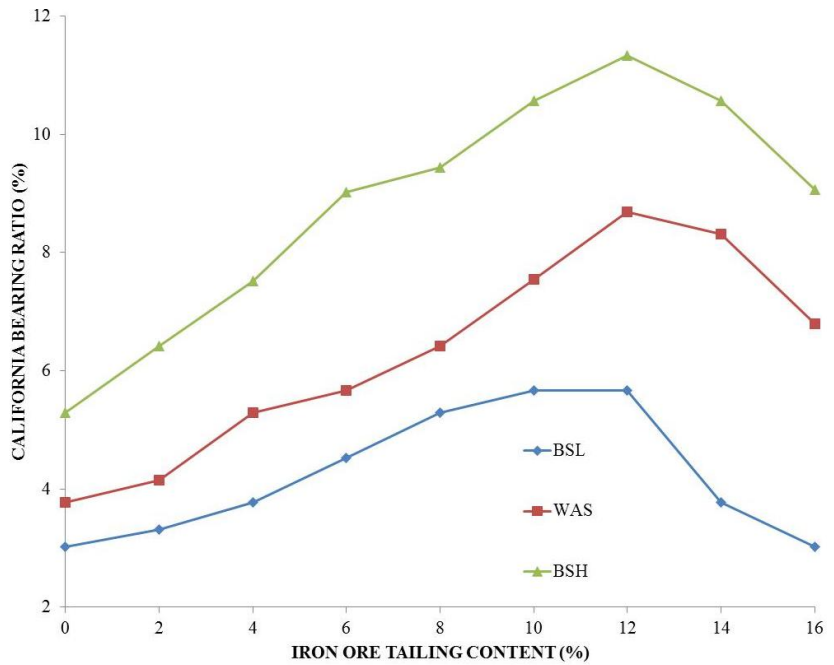

Fig. 4.15: Variation of California bearing ratio (24 hours soaking period) with iron ore tailing content

compactive effort, CBR values increased to peak values of 6, 9 and 11 % for BSL, WAS and BSH compaction respectively at 12 % IOT content. The recorded soaked CBR values did not meet the 30 % requirement for sub-bases both when compacted at optimum moisture content and at 100 % West African Standard compaction. Detailed test results are given in Table A4.10(b) of Appendix A.

Results of analysis of variance (ANOVA) for CBR (soaked for 24 hours) of black cotton soil – iron ore tailing mixtures are given in Table 4.8. For BSL, WAS and BSH compactions the results show that the effect of IOT on the soaked CBR was not statistically significant for BSL ($F_{CAL} = 4.10 < F_{CRIT} = 4.49$), WAS ($F_{CAL} = 0.79 < F_{CRIT} = 4.49$) and BSH ($F_{CAL} = 0.16 < F_{CRIT} = 4.49$). Detailed test results are given in Table B4.6(d, e and f) of Appendix B.

Results of two-way analysis of variance (ANOVA) for California bearing ratio of iron ore tailing-compactive effort are summarised in Table 4.9. The results show that the effect of the iron ore tailing and compactive effort on the soaked CBR was statistically significant ($F_{CAL} = 9.51 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 65.63 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.12 of Appendix B.

4.7 Microanalysis

Microstructure of specimens before and after treatment with optimal concentration of IOT were observed on the Scanning Electron Microscope (SEM). The objectives were to obtain a SEM micrograph to investigate the bond formation, the surface texture, the

mineral structure and geometry of the element due to the curing and iron ore tailing-soil interaction (Saravut et al., 2012).

4.7.1 7 days curing period micrographs for British Standard light compaction

The micrographs of UCS specimens of the natural soil and 10 % IOT treated black cotton soil cured for 7 days are shown on Plates 4.1 and 4.2, respectively.

The micrograph of the natural soil after 7 days curing shows that the soil was cohesive

Comment [KJ06]: It is better to place the plates beside each other for comparative purpose.

Plate 4.2: Micrograph of black cotton soil - 10 % iron ore tailing mixture

(7 days curing)

As IOT was added to the soil there was a slight reduction in the cohesiveness of the soil due to the cation exchange reaction which forced the weakly bonded ions in the clay structure to be substituted by the more active and higher valent cations and this led to the flocculation and liberation of water bonded at the outer layers (Asma and Dariusz, 2013).

4.7.2 28 days curing period micrographs for British Standard light compaction

The micrographs of UCS specimens of the natural and 10 % IOT treated black cotton soil cured for 28 days are shown on Plates 4.3 and 4.4, respectively. The micrograph of UCS specimens of the natural soil cured for 28 days is not significantly different from that of specimen cured for 7 days although their structural particle arrangements appear to be different. This could be attributed to lesser inter-surface activity that might have taken place during curing.

Comment [KJ07]: It is better to place the plates beside each other for comparative purpose.

Plate

Plate 4.4: Micrograph of black cotton soil - 10 % iron ore tailing mixture
(28 days curing)

The micrograph of black cotton soil – 10 % IOT mixture cured for 28 days gives a better view of how the sample became coarser than those of specimens cured for 7 days. A complete reaction of the soil-iron ore tailing mixture might have taken place with complete cation exchange and the gain in full strength after 28 days (Sani, 2012).

4.8 Durability

In order to simulate the worst condition that could occur in the field, durability was evaluated by the immersion of specimens in water to determine resistance to loss in strength which is more acceptable for tropical regions like Nigeria (Ola, 1974). The resistance to loss in strength was determined as the ratio of the unconfined compressive strength of specimen cured for 7 days, and later immersed in water for 7 days, to those cured for 14 days. Conventionally, an allowable 20% loss in strength is recommended for a specimen cured for 7 days and immersed in water for 4 days (Ola, 1974; Osinubi, 1998a; 1999).

The variation of resistance to loss in strength of black cotton soil with iron ore tailing content for BSL, WAS and BSH compactions is shown in Fig. 4.16. For BSL, WAS and BSH compactions, resistance to loss in strength increased from 10.81 % (i.e., loss in strength of 89.19 %), 11.84 % (i.e., loss in strength of 88.16%) and 13.09 % (i.e., loss in strength of 86.91%) % for the natural black cotton soil to peak values of 24.71% (i.e., loss in strength of 75.29 %), 24.73 % (i.e., loss in strength of 75.27 %) and 17.18 % (i.e., loss in strength of 82.82 %) at 8, 12 and 10 % IOT contents, respectively.

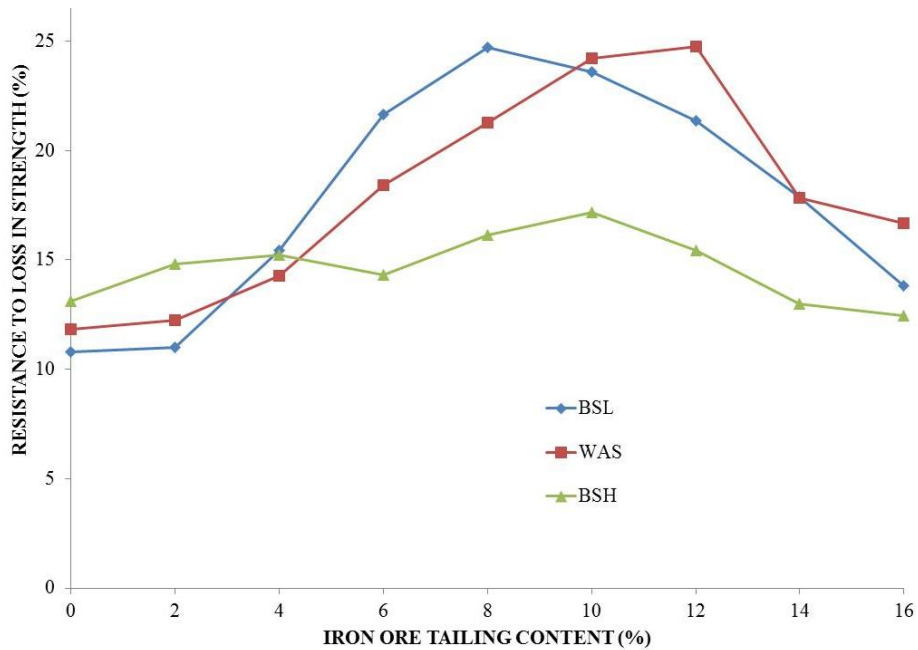

Fig. 4.16: Variation of resistance to loss in strength of black cotton soil with iron ore tailing content

The recorded peak resistance to loss in strength value of 24.73 % is above 20 % as required maximum. This implies that the IOT stabilized black cotton soil sample did not meet the minimum durability requirement for use in pavement construction. Detailed test results are given in Table A4.11 of Appendix A.

Results of analysis of variance (ANOVA) for durability of black cotton soil – iron ore tailing mixtures are given in Table 4.10. For BSL, WAS and BSH Compactions the results show that the effect of IOT on the durability was statistically significant for BSL ($F_{CAL} = 14.86 > F_{CRIT} = 4.49$), WAS ($F_{CAL} = 16.92 > F_{CRIT} = 4.49$) and BSH ($F_{CAL} = 12.13 > F_{CRIT} = 4.49$) compactive efforts. Detailed test results are given in Table B4.7 of Appendix B.

Table 4.10: Results of analysis of variance for durability of black cotton soil - iron ore tailing mixtures

Results of two-way analysis of variance (ANOVA) for durability of iron ore tailing-compactive effort are summarised in Table 4.11. The results show that the effect of the iron ore tailing and compactive effort on the durability was statistically significant ($F_{CAL} = 5.65 > F_{CRIT} = 2.59$) for IOT and ($F_{CAL} = 4.58 > F_{CRIT} = 3.63$). The effect of compactive effort was more significant than that of iron ore tailing. Detailed test results are given in table B4.13 of Appendix B.

CHAPTER FIVE

CONCLUSION AND RECOMMENDATION

5.1 Conclusion

The preliminary investigation conducted on the natural black cotton soil collected at Baure, in Deba L.G.A of Gombe State shows that it falls under A-7-6 (13) classification for AASHTO (1986) and CH according to Unified Soil Classification System (ASTM, 1992). The natural soil has low moisture content of 15.17 %, liquid limit of 64.5 %, plastic limit of 25 %, plasticity index of 39.5 %, linear shrinkage of 27.14 %, free swell of 85 %, and specific gravity of 2.42. These values indicate that the soil is of high plasticity with about 74.7 % of the soil particles passing the BS. No 200 sieve.

The gradation of the black cotton soil improved as the iron ore tailing (IOT) content increased. The Atterberg limits showed that the liquid limit increased from 64.5 % of the natural at 0 % IOT to 71 % at 2 % IOT content then decreased to 59.9 % at 16 % IOT content. Plastic limit increased from a natural soil value of 25 % to a peak value of 34.9 % at 8 % IOT content and then reduced to 27.46 % at 16 % IOT content. The plasticity index reduced from the natural soil value of 39.5 % to 32.44 % at 16 % IOT content.

The maximum dry density (MDD) of black cotton soil increased with higher IOT content and compactive efforts from 1.38, 1.52 and 1.59 Mg/m³ for the natural soil when compacted using British Standard light (BSL), West African Standard (WAS) and British standard heavy (BSH) energies, respectively, to 1.53, 1.66 and 1.72 Mg/m³, at 16 % IOT content.

The optimum moisture content (OMC) values decreased from 28.5, 18.5 and 16.5% for the natural black cotton soil to minimum values of 22, 14 and 11.5 % at 16, 14

and 14% IOT contents when compacted at the energy levels of the BSL, WAS and BSH, respectively.

The 7 day unconfined compressive strength (UCS) values for BSL, WAS and BSH compactive efforts recorded for the natural black cotton soil were 172.59, 328.36 and 448.83 kN/m², respectively. The UCS values of the treated soil increased to 337.77, 479.44 and 821.57 kN/m² at 16, 12 and 12 % IOT content, respectively, for the three energy levels considered. These did not meet the 1710 kN/m² prescribed by Road Note 31 for economic range of ordinary Portland cement stabilization.

The soaked CBR values of 3, 4 and 5 % for the natural black cotton soil compacted with BSL, WAS and BSH energies, respectively, increased to peak values of 6, 9 and 11 %, respectively, when treated with 12 % IOT. None of the recorded peak CBR values for the three energy levels meets the minimum requirement of 15 % prescribed by the Nigerian General Specifications, section vi, clause 6201 for subgrade materials compacted at the BSL energy level.

The resistance to loss in strength of black cotton soil increased from 10.81, 11.84, and 13.09 % for the natural soil to peak values of 24.71, 24.73 and 17.18 % for BSL, WAS and BSH compaction energies at 8, 12, and 10 % IOT contents, respectively. The recorded peak resistance to loss in strength of value (75.29 %) fell short of the acceptable conventional 80 % accepted as maximum resistance to loss in strength.

Based on the foregoing, an optimal 10 % iron ore tailing treatment of black cotton soil when compacted with British Standard heavy energy can be used as sub base material in road construction.

5.2 Recommendation

Based on the results obtained in this study:

1. An optimal 10 % iron ore tailing content can be used to improve the properties of black cotton soil when compacted with BSH energy.
2. Iron ore tailing (IOT) cannot be used as a stand-alone stabilizer but should be used as admixture in lime or cement stabilization of black cotton soil.

APPENDIX A

Comment [KJO10]: Correct text of titles as shown

Table A4.1: Results of specific gravity of iron ore tailing

Flask No	K23	L91	L10
Mass of Bottle M1	20.7	23	18.1
Mass of Bottle + Soil M2	25.3	27.8	23
Mass of Bottle + Soil + Water M3	49	51.3	46.8
Mass of Bottle + Water M4	45.6	47.8	43.2
M2 - M1	4.6	4.8	4.9
M4 - M1	24.9	24.8	25.1
M3 - M2	23.7	23.5	23.8
(M4 - M1) - (M3 - M2)	1.2	1.3	1.3
$G_s = (M2-M1) / ((M4-M1)-(M3-M2))$	3.8333	3.6923	3.7692
Average Gs	3.76		

Table A4.2: Results of specific gravity of black cotton soil - iron ore tailing mixtures

IOT content %	specific gravity
0	2.42
2	2.46
4	2.52
6	2.64
8	2.68
10	2.74
12	2.79
14	2.83
16	2.88

Table A4.3: Results of moisture content of natural black cotton Soil

Container No	X46	1Q	M15
Mass of Container M1	10.2	11.6	13.6
Mass of Container + Wet Soil M2	77	89.7	84.2
Mass of Container + Dry Soil M3	68.21	79.4	74.9
Mass of Dry Soil (M3-M1) = Ws	58.01	67.8	61.3
Mass of Wet Soil (M2- M1)	66.8	78.1	70.6
Ww = (M2-M10)-(M3-M1)	8.79	10.3	9.3
Moisture Content = W = Ww/Ws	15.153	15.192	15.171
Average W	15.17
